

Ex:

Choose a reference node and use the node-voltage method to find the remaining node voltages.

**SOL'N:** Node voltages shift up or down, depending on which node is chosen as the reference node. The choice is arbitrary. Here, the reference node will be below the  $7\ \Omega$  resistor.

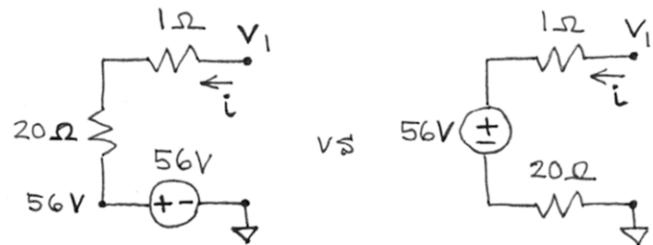

We find that  $v_2$  and  $v_3$  are known values, owing to the  $16\text{ V}$  and  $30\text{ V}$  sources connected in series to the reference node, (with no series resistors).

We have only the  $v_1$  node to solve for. The summation of currents out of the  $v_1$  node yields the following eq'n:

$$\frac{v_1 - 56\text{ V}}{1\ \Omega + 20\ \Omega} + \frac{v_1}{7\ \Omega} + 4\text{ A} = 0\text{ A}$$

Note: The first term of the current summation is found by sliding the  $20\Omega$  resistor thru the  $56V$  source.

The current  $i$  is the same in both circuits:

$$i = \frac{V_1 - 56V}{1\Omega + 20\Omega}$$

Returning to the eq'n for  $V_1$ , we group together the terms multiplying  $V_1$  and move constants to the right side:

$$V_1 \left( \frac{1}{21\Omega} + \frac{1}{7\Omega} \right) = \frac{56V}{21\Omega} - 4A$$

Multiplying both sides by  $21\Omega$  yields the following:

$$V_1 (1+3) = 56V - 21\Omega (4A) = 56V - 84V$$

or

$$V_1 = -\frac{28V}{4} = -7V$$

Note: The currents flowing out of the  $V_1$  node are  $-3A$  to the left,  $-1A$  down, and  $4A$  to the right. The sum is zero. ✓
